1 - NAME AND INTENDED USE

The Bio-Rad MONOLISA™ Anti-HBs EIA is a qualitative and quantitative enzyme immunoassay for the detection of antibody to hepatitis B surface antigen in human serum and EDTA, heparin, or citrated plasma. The assay results may be used as an aid in the determination of susceptibility to hepatitis B virus (HBV) infection in individuals prior to or following HBV vaccination or where vaccination status is unknown. Assay results may be used with other HBV serological markers for the laboratory diagnosis of HBV disease associated with HBV infection. A reactive assay result will allow a differential diagnosis in individuals displaying signs and symptoms of hepatitis in whom etiology is unknown. The MONOLISA™ Anti-HBs EIA is intended for manual use and for use with the Bio-Rad EVOLIS™ Automated Microplate System in the detection of antibody to hepatitis B surface antigen.

WARNING: This assay has not been FDA cleared or approved for the screening of blood or plasma donors.

Federal law restricts this device to sale by or on the order of a physician.

Assay performance characteristics have not been established for immunocompromised or immunosuppressed patients. The user is responsible for establishing their own assay performance characteristics in these populations.

2 - SUMMARY AND EXPLANATION OF THE TEST

Hepatitis B Virus (HBV) is a major public health problem, with more than 400 million people chronically infected worldwide.¹ Chronic hepatitis B is a leading cause of cirrhosis and liver cancer. The virus is transmitted efficiently by a number of routes, including passage from mother to child and percutaneous or permucosal exposure to infectious blood or body fluids.² Sexual contact, intravenous drug use, blood transfusion, tissue transplantation, and hemodialysis procedures may transmit the
disease.\textsuperscript{3,4} Immunization with a licensed HBV vaccine is a highly effective strategy to prevent HBV transmission, with protection achieved in over 95% of all vaccinees.\textsuperscript{5,6}

The genetic organization, transcription, and replication of the virus are well understood.\textsuperscript{7,8} The whole virion, or Dane particle, contains an envelope, consisting of a lipid bilayer and glycoproteins (surface antigens), and a core (nucleocapsid) that encloses a circular DNA genome. The viral DNA encodes at least seven proteins from four open reading frames [surface (S), core (C), polymerase (P), and the X gene (X)]. The proteins that are important diagnostically are surface antigen (HBsAg), core antigen (HBcAg) and e antigen (HBeAg), a hidden epitope released by disruption of the nucleocapsid.

During the early stages of primary infection by hepatitis B virus, HBV DNA, as well as HBsAg and HBeAg, are readily detectable. As the host mounts an immune response, the first antibodies to appear are antibodies to the core antigen (anti-HBc), followed by anti-HBe and finally anti-HBs, which marks the immune stage.\textsuperscript{9} In adults with normal immune function, most (94% - 98%) recover completely from newly acquired HBV infection, clearing the virus from the blood and producing neutralizing antibodies during convalescence.\textsuperscript{10,11} However, in some patients, HBsAg may persist for months or years and anti-HBs is undetectable, indicating a chronic disease state. The clinical course for an individual patient may be influenced by genetic differences in the host immune response, as well as the patient’s age at the time of infection, sex, treatment with immunosuppressive agents, and the appearance of HBV mutants.

The presence of anti-HBs antibodies is an important factor in the diagnosis and prognosis of HBV infection, indicating previous exposure to HBV and acquired immunity. Anti-HBs is used in epidemiological surveillance studies, to assess past exposure to Hepatitis B in potential Hepatitis B vaccine recipients, to monitor the vaccination process, and to select plasma with high antibody concentrations for the manufacture of therapeutic immune
globulin. The determination of anti-HBs levels has been standardized by means of the WHO Anti-HBs Reference Preparation, and a level greater than or equal to 10 milli-International Units per milliliter (10 mIU/mL) is considered protective against HBV infection. The verification of at least a minimum anti-HBs titer of 10 mIU/mL, that is, an immunity threshold titer, is crucial for the appropriate management of vaccinated individuals who may subsequently be exposed to HBsAg-positive fluids and specimens.

3 - BIOLOGICAL PRINCIPLES OF THE PROCEDURE

The MONOLISA™ Anti-HBs EIA is an enzyme immunoassay (direct antibody sandwich format) which utilizes polystyrene microwells coated with native HBsAg (human, subtypes ad and ay) as the solid phase and a conjugate containing horseradish peroxidase-labeled HBsAg (human, subtypes ad and ay). In the assay procedure, patient specimens and controls are incubated in the antigen-coated microwells. If antibodies to HBs are present in a specimen or control, they bind to the antigen. Excess sample is removed by a wash step. The conjugate is then added to the microwells and allowed to incubate. The conjugate binds to any antigen-antibody complexes present in the microwells. Excess conjugate is removed by a wash step, and a chromogen/substrate solution is added to the microwells and allowed to incubate. If a sample contains anti-HBs, the bound enzyme (HRP) causes the colorless tetramethylbenzidine (TMB) in the chromogen solution to change to blue. The blue color turns yellow after the addition of a stopping solution. If a sample does not contain anti-HBs, the chromogen/substrate solution in the well remains colorless during the substrate incubation, and after addition of the stopping solution. The color intensity, measured spectrophotometrically, is proportional to the amount of anti-HBs present in the specimen. Absorbance value readings for patient specimens are compared to a cutoff value determined by the 10 mIU/mL calibrator, which is calibrated against the WHO reference standard.

### MONOLISA™ Anti-HBs EIA Product Description

**Product No. 25220 (192 Tests)**

<table>
<thead>
<tr>
<th>Component</th>
<th>Contents</th>
<th>Preparation</th>
</tr>
</thead>
</table>
| **R1** • Anti-HBs EIA Microwell Strip Plates (2) | • Microwell strips in holder, coated with HBsAg (human \(a\) and \(\alpha\) subtypes)  
• Tabs are labeled “EE”  
• ProClin (trace) | Use as supplied. Return unused strips to the pouch. Do not remove desiccant. |
| **R2** • Wash Solution Concentrate (30X)  
1 bottle (120 mL) | • Sodium Chloride  
• Tween 20 | Dilute 1:30 with deionized water. Clinical laboratory reagent water is acceptable. |
| **R3** • Anti-HBs EIA Specimen Diluent  
1 bottle (10 mL) | • Bovine proteins  
• Buffer with protein stabilizers  
• ProClin 300, 0.1%  
• Sample indicator dye | Use as supplied. |
| **C0** • Anti-HBs EIA Negative Control  
1 vial (1.5 mL) | • Human serum/plasma; negative for HIV and HCV antibodies and HBsAg  
• Gentamicin, 0.005%  
• ProClin 950, 0.16% | Use as supplied. |
| **C1** • Anti-HBs EIA Positive Control  
1 vial (1.5 mL) | • Anti-HBs Immunoglobulin (Human) therapeutic grade  
• Human serum/plasma; negative for HIV and HCV antibodies and HBsAg  
• Gentamicin, 0.005%  
• ProClin 950, 0.16%  
• Red dye | Use as supplied. |
| **C3** • Anti-HBs EIA 10 mIU/mL Calibrator  
1 vial (1.8 mL) | • Buffer with bovine proteins  
• ProClin 950, 0.16%  
• Anti-HBs Immunoglobulin (Human), therapeutic grade, 10 mIU/mL  
• Yellow dye | Use as supplied. |
| **R4** • Anti-HBs EIA Conjugate Concentrate (11X)  
1 bottle (3.0 mL) | • HBsAg (human \(a\) and \(\alpha\) subtypes) conjugated to HRP  
• Buffer with protein stabilizers  
• Gentamicin, 0.005%  
• ProClin 300, 0.5%  
• Green dye | Dilute in Anti-HBs EIA Conjugate Diluent as described. |

| R5 • Anti-HBs EIA Conjugate Diluent 2 bottles (15 mL) | • Buffer with protein stabilizers  
• Calf Serum  
• ProClin 300, 0.1% | Ready to use as described under Working Conjugate Solution. |
| R8 • Substrate Buffer 1 bottle (120 mL) | • Hydrogen Peroxide  
• Citric Acid/Sodium Acetate buffer  
• Dimethylsulfoxide (DMSO) | Ready to use as described under Working TMB Solution. |
| R9 • Chromogen (11X) 1 bottle (12 mL) | • Tetramethylbenzidine (TMB)* | Dilute with Substrate Buffer as described. |
| R10 • Stopping Solution 1 bottle (120 mL) | • 1N H₂SO₄ (Sulfuric Acid) | Use as supplied. |

* NOTE: Tetramethylbenzidine is a non-carcinogenic and non-mutagenic chromogen for peroxidase.¹²,¹³

Store the kit at 2-8°C. Bring all reagents except Conjugate Concentrate to room temperature (18-30°C) before use. Return reagents to 2-8°C immediately after use. Keep kit components within the closed kit box to prevent exposing the Conjugate Diluent to light during storage at 2-8°C. Store all unused strips/plates in pouch and reseal. Do not remove desiccant. Store strips/plates at 2-8°C.

5 - WARNINGS FOR USERS
For in vitro diagnostic use only.

1. This test kit should be handled only by qualified personnel trained in laboratory procedures and familiar with their potential hazards. Wear appropriate protective clothing, including lab coat, eye/face protection, and disposable gloves (synthetic, non-latex gloves are recommended) and handle with the requisite Good Laboratory Practices. Wash hands thoroughly after performing the test.

2. Do not smoke, drink, or eat in areas where specimens or kit reagents are being handled.

3. Do not pipette by mouth.
4. The following is a list of potential chemical hazards contained in some kit components (See Section 4 - Reagents):

a. **WARNING:** Components R3, R4 and R5 contain **0.1% or 0.5% ProClin 300**

   - **H317:** May cause allergic skin reaction.
   - **P280:** Wear protective gloves/protective clothing/eye protection/face protection.
   - **P302 + P352:** IF ON SKIN: Wash with plenty of soap and water.
   - **P333 + P313:** If skin irritation or rash occurs: Get medical advice/attention.
   - **P501:** Dispose of contents and container in accordance with local, regional, national, and international regulations.

**ProClin 300** (0.1% or 0.5%) is a biocidal preservative that is irritating to eyes and skin, may be detrimental if enough is ingested, and may cause sensitization by skin contact; prolonged or repeated exposure may cause allergic reaction in certain sensitive individuals.

b. **0.005% Gentamicin Sulfate**, a biocidal preservative, which is a known reproductive toxin, photosensitizer, and sensitizer; prolonged or repeated exposure may cause allergic reaction in certain sensitive individuals.
c. **DANGER! The Stopping Solution (R10) contains 1N Sulfuric Acid**

![Danger Symbol]

**H314:** Causes severe skin burns and eye damage.

**P290:** May be corrosive to metals.

**P280:** Wear protective gloves/protective clothing/eye protection/face protection.

**P301 + P330** IF SWALLOWED: Rinse mouth. Do NOT induce vomiting

**P305 + P351** IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.

**P305 + P351** IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.

**P501:** Dispose of contents and container in accordance to local, regional, national, and international regulations.

The 1N Sulfuric Acid (H$_2$SO$_4$) Stopping Solution is severely irritating or corrosive to eyes and skin, depending on the amount and length of exposure; greater exposures can cause eye damage, including permanent impairment of vision. In case of contact with eyes, rinse immediately with plenty of water and seek medical advice. Keep away from strong bases, reducing agents, and metals; do not pour water into this component. Waste from this material is considered hazardous acidic waste. However, if permitted by local, regional, and national regulations, it can be neutralized to pH 6-8 for non-hazardous disposal if operators are trained and equipped to do so.

5. **MONOLISA™ Anti-HBs EIA** contains human blood components. No known test method can offer complete assurance that infectious agents are absent. Therefore, all human blood derivatives, reagents, and human specimens should be handled as if capable of transmitting infectious disease, following recommended *Standard and Universal Precautions* for bloodborne pathogens as defined by OSHA$^{14}$, the guidelines from the current CDC/NIH *Biosafety in Microbiological and Biomedical Laboratories*$^{15}$, WHO
Laboratory Biosafety Manual\textsuperscript{16}, and/or local, regional, and national regulations.\textsuperscript{16-17} The following human blood derivatives are found in this kit:

a. Human source material used in the preparation of the Negative Control (C0) and as a diluent for the Positive Control (C1) is nonreactive for detectable hepatitis B surface antigen (HBsAg), and antibodies to hepatitis B core antigen, hepatitis C virus (HCV), and human immunodeficiency viruses (HIV-1 and HIV-2).

b. The human anti-HBs immunoglobulin used in the preparation of the Positive Control (C1) and Calibrator (C3) is a therapeutic grade material which has been inactivated.

c. The human plasma derived viral antigen HBsAg subtypes \textit{ad} and \textit{ay} used in the preparation of the Microplate (R1) and Conjugate Concentrate (R4) are highly purified and heat treated.

6. Biological spills: Human source material spills should be treated as potentially infectious. Spills not containing acid should be immediately decontaminated, including the spill area, materials, and any contaminated surfaces or equipment, with an appropriate chemical disinfectant that is effective for the potential biohazards relative to the samples involved (commonly a 1:10 dilution of bleach, 70-80\% Ethanol or Isopropanol, an iodophor [such as 0.5\% Wescodyne\textsuperscript{TM} Plus], or a phenolic, etc.) and wiped dry.\textsuperscript{18-20} Spills containing acid should be appropriately absorbed (wiped up) or neutralized, wiped dry and then the area should be decontaminated with one of the chemical disinfectants; materials used to absorb the spill may require biohazardous waste disposal.

\textbf{NOTE: DO NOT PLACE SOLUTIONS CONTAINING BLEACH INTO THE AUTOCLAVE.}
7. Dispose of all specimens and material used to perform the test as though they contain an infectious agent. Laboratory chemical and biohazardous wastes must be handled and discarded in accordance with all local, regional, and national regulations.

8. Complete hazard information and precautions are located in the Safety Data Sheets (SDS) available at www.bio-rad.com and upon request.

6 - PRECAUTIONS FOR USERS

1. The Bio-Rad MONOLISA™ Anti-HBs EIA is intended for the detection of antibody to hepatitis B surface antigen and does not detect HBsAg. The tabs at the end of the microwell strips are labeled with product code “EE”. The Bio-Rad GS HBsAg EIA 3.0 is intended for the detection of hepatitis B surface antigen, and does not detect antibody to HBsAg.

2. Do not use any kit components beyond their stated expiration date.

3. Any lot number of the following reagents may be used with this assay provided they have the correct catalog number and are not used beyond their labeled expiration date:
   - Chromogen (R9) - Catalog # 26182
   - Substrate Buffer (R8) - Catalog # 26181
   - Wash Solution Concentrate (R2) - Catalog # 25261
   - Stopping Solution (R10) - Catalog # 25260
   
   Do not mix any other reagents from different lot numbers.

4. Exercise care when opening vials and removing aliquots to avoid microbial contamination of the reagents.

5. Use a clean, disposable container for the conjugate. Exposure of the conjugate to sodium azide will result in its inactivation.

6. Avoid exposing Conjugate Diluent, Working Conjugate, Chromogen, or Working TMB Solution to strong light during storage or incubation. Do not allow the Working
TMB Solution to come into contact with any oxidizing agents.

7. Avoid contact of the Stopping Solution with any oxidizing agent. Do not allow Stopping Solution to come into contact with metals.

8. Use clean, polypropylene containers to prepare and store the Working TMB Solution. If glassware must be used, pre-rinse thoroughly with 1N sulfuric or hydrochloric acid followed by at least three washes of deionized water. Be sure that no acid residue remains on the glassware.

9. For the manual pipetting of controls and specimens, use individual pipette tips to eliminate carryover of samples.

10. Handle the Negative and Positive Controls and the 10 mIU/mL Calibrator in the same manner as patient specimens.

11. Use only adequately calibrated equipment with this assay.

12. Use of dedicated equipment is recommended if equipment performance validations have not precluded the possibility of cross-contamination.

13. The MONOLISA™ Anti-HBs EIA Procedure and the Interpretation of Results must be followed when testing serum or plasma specimens for the presence of antibodies to HBsAg. The user of this kit is advised to read the package insert carefully prior to conducting the test. In particular, the test procedure must be carefully followed for sample and reagent pipetting, plate washing, and timing of the incubation steps. Inadequate adherence to package insert instructions may result in erroneous results.

14. Failure to add specimen or reagent as instructed in the procedure could result in a falsely negative test. Repeat testing should be considered where there is clinical suspicion of procedural error.

15. An absorbance value of less than 0.000 AU may indicate a procedural or instrument error that should be evaluated. That result is invalid and that specimen must be re-run. If
repeated results are < 0.000, the performance of the instrumentation should be investigated.

16. Factors that can affect the validity of results include failure to add the specimen to the well, inadequate washing of microplate wells, failure to follow stated incubation times and temperatures, addition of wrong reagents to wells, the presence of metals, or splashing of bleach into wells.

7 - REAGENT PREPARATION AND STORAGE

**Working Conjugate Solution (R4 + R5)**

Bring Conjugate Diluent (R5) to room temperature. Place the Conjugate Diluent in a dark drawer or cupboard, or use other means to protect it from light while it is warming. Invert Diluent (colorless to pale straw) and Conjugate Concentrate (R4, green) to mix before using. Prepare a 1:11 dilution for each strip to be tested by adding 100 μL of Conjugate Concentrate to each 1 mL of Conjugate Diluent in a clean, polypropylene tube. Use the table below as a guide. Mix well but gently to avoid foaming. Working Conjugate Solution should be green. Note Concentrate lot number, date and time of preparation, and date and time of expiration of the Working Conjugate Solution. Alternatively, Working Conjugate Solution can be prepared by pipetting 1.5 mL of the Conjugate Concentrate into one bottle (15 mL) of the Conjugate Diluent. Working Conjugate Solution is stable for 30 hours at room temperature, and for 1 month if stored at 2-8°C. Studies have demonstrated no adverse effects from cycling the Working Conjugate Solution between 2-8°C and room temperature (18-30°C) multiple times (e.g., 10 cycles of 3 hours at room temperature followed by 2-8°C). **Working Conjugate Solution should be protected from light**, both at room temperature and at 2-8°C. For example, store the Working Conjugate Solution in a dark drawer or cupboard at room temperature until needed. Always mix working solution by inverting just prior to use.
Return unused Conjugate Concentrate to the refrigerator immediately after use. To avoid contamination of Conjugate, wear clean gloves and do not touch tips of pipettes.

Ensure that the volume of diluted reagent that is prepared will be adequate for the entire run. Use the following table as a guide for Working Conjugate Solution preparation:

**Preparation of Working Conjugate Solution by Number of Strips Used**

**Working TMB Solution (R8 + R9)**

Bring Chromogen (R9) and Substrate Buffer (R8) to room temperature. Invert the Chromogen and Substrate Buffer to mix before using. Prepare a 1:11 dilution for each strip to be tested by mixing 100 μL of Chromogen to each 1 mL of Substrate Buffer in a clean, polypropylene container. Note Chromogen lot number, date and time of preparation, and date and time of expiration (8 hours from preparation) on container. Mix TMB Working Solution gently prior to use. Working TMB Solution should be kept in the dark at room temperature and used within 8 hours of preparation.

Chromogen should be colorless to slightly yellow. Any other color indicates that the reagent is contaminated. Do not use this reagent. The Working TMB Solution should be colorless. A distinct blue color indicates that the reagent is contaminated. Discard the Working TMB Solution and prepare fresh reagent in a clean container.

Prepare only the amount of the reagent to be used within 8 hours, ensuring that the volume of diluted reagent will be adequate for the entire run. Extra Chromogen is provided. Use the following table as a guide:

Wash Solution (R2)
Prepare Wash Solution (R2) by adding one part Wash Solution Concentrate (30X) to 29 parts of deionized or distilled water (e.g., 120 mL of Wash Solution Concentrate to 3480 mL of deionized water). Clinical laboratory reagent water is acceptable. The diluted Wash Solution can be stored ambient for up to four weeks in a plastic container. Note the lot number, date prepared, and expiration date on the container. Discard if no suds are evident in the Wash Solution. Prepare a sufficient quantity of Wash Solution to complete a full run.

8 - SPECIMEN COLLECTION, PREPARATION, AND STORAGE

Serum or certain types of plasma may be used in the test. The following tube types and anticoagulants, including those in both glass and plastic tubes, have all been evaluated and found to be acceptable: SST, EDTA, sodium citrate, lithium heparin, and sodium heparin. Specimens that are collected into anticoagulant tubes should be filled as labeling indicates to avoid improper dilution. The volume of anticoagulant in sodium citrate tubes causes a specimen dilutional effect. Individuals with borderline results obtained from specimens collected in sodium citrate should be retested using serum specimens. Specimens with observable particulate matter should be clarified by centrifugation prior to testing.

Serum/plasma should remain at room temperature for no longer than eight hours. If assays are not completed within eight hours, serum/plasma should be refrigerated at 2-8°C. Specimens may be stored at 2-8°C for 7 days, including the time that samples
are in transit. Sera/plasma should be removed from the clot, red blood cells, or separator gel before storage. For long-term storage, the specimens should be frozen (at -20°C or lower), after removal from the clot, red blood cells, or separator gel. Specimens should not be used if they have incurred more than 5 freeze-thaw cycles. Mix specimens thoroughly after thawing.

Note: If specimens are to be shipped, they should be packed in compliance with Federal Regulations covering the transportation of etiologic agents. Specimens may be shipped frozen or on ice. For shipments that are in transit for more than 7 days, specimens should be kept frozen (-20°C) or lower. The total time after specimen collection and before testing, including time in transit, should not exceed 7 days unless specimens are frozen at -20°C.

9 - MONOLISA™ Anti-HBs EIA PROCEDURE

Materials Provided
See Reagents section on pages 7-8.

Optional Materials
MONOLISA™ Anti-HBs Calibrator Kit (Catalog # 25219).

Materials Required But Not Provided
1. Precision pipettes to deliver volumes from 25 μL to 200 μL, 1 mL, 5 mL, and 10 mL (accurate within ± 10%). A multichannel pipettor capable of delivering 100 μL is optional.
2. Pipette tips.
3. Appropriately sized graduated cylinders.
4. Dry-heat incubator capable of maintaining 37 ± 2°C.
5. Bio-Rad microwell plate or strip washer, or equivalent. The washer must be capable of dispensing 375 μL per well, cycling 5 times, and soaking for 30-60 seconds between each wash.
6. Bio-Rad microwell plate or strip reader or equivalent. The spectrophotometer should have the following specifications at wavelengths 450 nm and 405 nm:
   - Bandwidth: 10 nm HBW (Half Band Width) or equivalent
   - Absorbance Range: 0 to 2 AU (Absorbance Units)
   - Repeatability: ± (0.5% + 0.005) AU
   - Linearity or Accuracy: 1% from 0 to 2.0 AU

The instrument should contain a reference filter for reading at 615 nm to 630 nm.

7. The MONOLISA™ Anti-HBs EIA is approved for use with the Bio-Rad EVOLIS™ Automated Microplate System.

8. Household bleach (5% to 8% sodium hypochlorite) may be diluted to a minimum concentration of 10% bleach (or 0.5% sodium hypochlorite). Alternative disinfectants include: 70% ethanol or 0.5% Wescodyne™ Plus (West Chemical Products, Inc.).

9. Paper towels or absorbent pads for blotting.

10. Labeled null strips, for testing partial plates.

11. Clean polypropylene containers of appropriate size for the preparation of TMB (do not use polystyrene) and Conjugate Working Solutions.

12. Deionized or distilled water. Clinical laboratory reagent water is acceptable.

14. Laboratory timer.

15. EIA reagent reservoirs (optional).

16. Plate sealers (Catalog # 0210-00 or equivalent) are required, except on an approved microplate processor.

**Preliminary Statements**

1. The expected run time for this procedure is approximately 3 hours from initiation of the first incubation step. Each run of
this assay must proceed to completion without interruption after it has been started.

2. Controls to be included on each plate of this assay: Positive Control (run singly), Negative Control (run singly), and the 10 mIU/mL Cutoff Calibrator (run in triplicate). The cutoff for patient specimens is determined by the mean (\( \bar{x} \)) value of the 10 mIU/mL Calibrator replicates on each individual plate.

3. Specimens, Calibrators and Controls may be diluted in-well by one of two methods:
   a. Add 25 μL of Specimen Diluent to each well first, followed by 75 μL of specimen or control within 30 minutes, then mix gently to avoid foaming.
   b. Add 75 μL of specimen or control to each well first, followed by 25 μL of Specimen Diluent within 30 minutes, then mix gently to avoid foaming.

   Note: To maintain consistency in results, use only one of the above methods per plate.

4. Quantitative determinations for patient specimens with concentrations of antibody > 1000 mIU/mL may be obtained by prediluting in Working Wash Solution. The prediluted samples can then be processed according to the normal assay procedure, by diluting 3:4 in Specimen Diluent.

5. The procedure specifies the addition of 100 μL volumes of diluted specimen, Working Conjugate Solution, Working TMB Solution, and Stopping Solution while performing the assay. No adverse effects were noted when volumes from 90-150 μL were tested at each of these steps.

6. Do not splash controls, specimens, or reagents between microwells of the plate.

7. Cover plates for each incubation step using plate sealers or other appropriate means to minimize evaporation.

8. Avoid exposure of the plates to light during the final incubation step (following the addition of the Working TMB Solution).

10. Adhere to the recommended time constraints for the use of the Working TMB Solution (8 hours, ambient), Working Conjugate Solution (30 hours at ambient temperature, or 1 month at 2-8°C), and Wash Solution (4 weeks, ambient).

11. Avoid the formation of air bubbles in each microwell.

12. For additional procedural instructions when running this assay in qualitative, quantitative, or combination plate mode with the EVOLIS™ Automated Microplate System, consult the following documents:
   - EVOLIS™ MATRM, Assay Module MONOLISA™ Anti-HBs EIA
   - EVOLIS™ MATRM, Assay Module MONOLISA™ Anti-HBs EIA & Anti-HBc EIA
   - EVOLIS™ MATRM, Assay Module MONOLISA™ Anti-HBs EIA with Quantitative Determination using the MONOLISA™ Anti-HBs Calibrator Kit
   - EVOLIS™ Operator’s Manual

13. Microwell strips not needed for the assay may be returned to the plate pouch and sealed, and then used at a later time. Strips from different plates can only be mixed to assemble full or partial plates if they are from the same plate lot and have come from plates that have previously been tested with kit controls and yielded valid runs. When assembling a plate that contains strips from a newly opened, previously untested plate, one of these strips should be placed at the beginning of the plate and tested with the kit controls.

14. When testing with the EVOLIS™ Automated Microplate System, remove strips not needed for the assay and replace them with labeled null strips, as necessary. A minimum of 4 strips, including both assay strips and null strips, should be included on each plate in order to avoid excessive evaporation in the incubator. Fill the wells of each null strip with deionized water or Working Wash Solution so there are
a minimum of 4 strips that contain liquid. Set up the run in the EVOLIS™ for the actual samples being tested, and do not include the null strips in the assay setup.

15. Take care when assembling partial plates with coated and uncoated (null) strips, as automated systems cannot distinguish between the strips and will report results for all wells that are assigned a sample ID number (even if a null strip is inadvertently placed where sample IDs have been assigned).

16. Dry residue from the plate blocking process may be visible in the microwells. Assay results will not be affected by this material. Before reading the plates, carefully wipe the bottom of the plates to remove any material that remains on the outside of the wells, and ensure that all strips have been pressed firmly into place.

**Manual EIA Procedure**

The MONOLISA™ Anti-HBs EIA performance is dependent upon incubation times and temperatures. Temperatures outside of the validated ranges may result in invalid assays. Incubation temperatures should be carefully monitored using calibrated thermometers, or equivalent.

1. Perform equipment maintenance and calibration, where necessary, as required by the manufacturer.

2. **Bring all of the reagents except Conjugate Concentrate to room temperature before beginning the assay procedure.**

4. Remove strips not needed for the assay and replace them with labeled Null Strips, as necessary.

5. If specimen identity is not maintained by an automatic procedure, identify the individual wells for each specimen or control on a data sheet.
6. Dilute specimens, calibrators, and controls 3:4 in the Specimen Diluent:

Specimens, calibrators, and controls may be prediluted 3:4 in the Specimen Diluent prior to addition to the well (for example, dilute 150 μL of specimen in 50 μL of Specimen Diluent, mix gently to avoid foaming, and then transfer 100 μL to the well), or diluted in-well. (See previous Preliminary Statement No. 3 for details.)

NOTE: After adding the specimen, the diluent will change from purple to a blue color.

It is possible to verify the presence of samples in the wells by spectrophotometric reading at 620 nm (single wavelength). See Section 10 - Spectrophotometric Verification of Sample and Reagent Pipetting (Optional).

One well of Positive Control, one well of Negative Control, and three wells of the 10 mIU/mL Cutoff Calibrator must be assayed on each plate or partial plate of specimens when performing the qualitative procedure.

7. Cover the microwell plate with a plate sealer or use other means to minimize evaporation. **Incubate the plate for 60 ± 5 minutes at 37 ± 2°C.**

8. At the end of the incubation period, carefully remove the plate sealer and aspirate the fluid from each well into a biohazard container. **Wash the microwell plate or strip a minimum of five times** with the Wash Solution (at least 375 μL/well/wash), or as otherwise validated. **Soak each well for 30 to 60 seconds between each wash cycle.** Aspirate the Wash Solution after each wash. After the last wash, if excess liquid remains, blot the inverted plate on clean, absorbent paper towels. **NOTE: Grasp the plate holder firmly at the center of the long sides before inverting to blot.**

9. **Add 100 μL of the Working Conjugate Solution to each well containing a specimen, calibrator, or control.** Avoid bumping plates containing working conjugate solution to
prevent contamination of the plate sealer and/or top edges of the wells. **NOTE: The conjugate is colored green.** It is possible to verify the presence of conjugate in the wells by spectrophotometric reading at 615 nm to 630 nm (single wavelength). See Section 10 - Spectrophotometric Verification of Sample and Reagent Pipetting.

10. Cover the microwell plate with a plate sealer or use other means to minimize evaporation. **Incubate the plate for 60 ± 5 minutes at 37 ± 2°C.**

11. At the end of the incubation period, carefully remove the plate cover and aspirate the fluid in each well into a biohazard container. **Wash the microwell plate or strip a minimum of five times** with the Wash Solution (at least 375 μL/well/wash), or as otherwise validated. **Soak each well for 30 to 60 seconds between each wash cycle.** Aspirate the Wash Solution after each wash. After the last wash, if excess liquid remains, blot the inverted plate on a clean, absorbent paper towel. **NOTE: Grasp the plate holder firmly at the center of the long sides before inverting to blot.**

12. **Add 100 μL of the Working TMB Solution to each well containing a specimen, calibrator, or control. Incubate plates in the dark for 30 ± 5 minutes at room temperature (18-30°C).** (For example, cover the plates with black plastic or place in a drawer).

13. **Add 100 μL of Stopping Solution to each well** to terminate the reaction. Use the same sequence and rate of distribution as for the substrate solution addition. **Tap the plate gently,** or use other means to assure complete mixing. Complete mixing is required for acceptable results.

14. **Read absorbance within 30 minutes after adding the Stopping Solution, using the 450 nm filter with 615 nm to 630 nm as the reference.** (Blank on air.)
Decontamination
Dispose of all specimens and materials used to perform the test as though they contain an infectious agent. Disposal should comply with all applicable waste disposal requirements.

10-SPECTROPHOTOMETRIC VERIFICATION OF SAMPLE AND REAGENT PIPETTING (OPTIONAL)

Verification of Sample Pipetting
After the sample addition to the Specimen Diluent, the purple diluent turns blue.

The presence of sample in the well can be verified by spectrophotometric reading at 620 nm (single wavelength).

- The O.D. values of the wells containing sample or control diluted in Specimen Diluent (R3) must be greater than or equal to 0.250. A value lower than this indicates poor dispensing of the sample or control.

Verification of the Conjugate Dispense
The Conjugate (R4) is green in color.

The presence of Conjugate (R4) in the well can be verified by spectrophotometric reading at 615 nm to 630 nm (single wavelength):

- The O.D. value of each well must be greater than or equal to 0.100. A value lower than this indicates poor dispensing of the Working Conjugate Solution.

11-QUALITY CONTROL - VALIDATION OF RESULTS
Each plate should contain a Positive Control, a Negative Control, and three Cutoff Calibrators. The Positive and Negative Controls are intended to monitor for substantial reagent failure. The Positive Control will not ensure precision at the assay cutoff. In addition, the quality control supplied in the MONOLISA™ Anti-HBs EIA is in a serum matrix and may not adequately
control the assay for plasma specimens. The user should include alternate control material for plasma matrices.

The test is invalid and must be repeated if the absorbance readings of the controls and the calibrator do not meet specifications. If the test is invalid, patient results cannot be reported. Quality control testing must be performed in conformance with local, state, and/or federal regulations, or accreditation requirements, and your laboratory’s standard Quality Control procedures. It is recommended that the user refer to NCCLS C24-A3 and 42 CFR 493.1256 for guidance on appropriate QC practices.

The 10 mIU/mL Cutoff Calibrators must meet both the absorbance and precision criteria listed below.

The individual absorbance value of each 10 mIU/mL Cutoff Calibrator must be greater than or equal to 0.050 and less than or equal to 0.150.

Individual Cutoff Calibrator absorbance values must be within the range $0.65 \times \text{CAL}_{10\bar{x}}$ to $1.35 \times \text{CAL}_{10\bar{x}}$.

If the Cutoff Calibrators do not meet these acceptance criteria, the run is invalid and must be repeated.

**Cutoff Value Example:**

<table>
<thead>
<tr>
<th>10 mIU/mL Cutoff Calibrator</th>
<th>Sample Number</th>
<th>Absorbance</th>
<th>Total Absorbance</th>
<th>( = \frac{0.332}{3} = 0.111 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sample Number</td>
<td>Absorbance</td>
<td>Total</td>
<td>( = 0.332 )</td>
<td>( = 0.111 ) (CAL_{10\bar{x}})</td>
</tr>
<tr>
<td>1</td>
<td>0.113</td>
<td>3</td>
<td>0.332</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>0.109</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>0.110</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

All three 10 mIU/mL Cutoff Calibrator values above are within the range of 0.65 to 1.35 times the CAL_{10\bar{x}} as shown by the calculation below:

\[
0.65 \times \text{CAL}_{10\bar{x}} = 0.65 \times 0.111 = 0.072 \\
1.35 \times \text{CAL}_{10\bar{x}} = 1.35 \times 0.111 = 0.150 \\
\text{Therefore, the acceptance range is 0.072 to 0.150.}
\]
The mean absorbance of the 10 mIU/mL Cutoff Calibrators (CAL10) is the Cutoff Value for the assay.

Assay Validation
A run is valid if the following criteria are met:

- The absorbance value of the Positive Control must be greater than or equal to 0.600 AU (PC ≥ 0.600).
- The individual absorbance value of each 10 mIU/mL Cutoff Calibrator (CAL10i) must be greater than or equal to 0.050 and less than or equal to 0.150 AU (0.050 ≤ CAL10i ≤ 0.150). All Cutoff Calibrator absorbance values must also be within the range 0.65 X CAL10 to 1.35 X CAL10 (0.65 X CAL10 ≤ CAL10i ≤ 1.35 X CAL10). If the Cutoff Calibrators fail to meet these acceptance criteria, the run is invalid and must be repeated.
- The absorbance value of the Negative Control must be greater than 0.000 AU and less than or equal to 0.100 AU (0.000 < NC ≤ 0.100).
- The absorbance value of the Negative Control must be less than the mean of the absorbance values of the 10 mIU/mL Cutoff Calibrator, that is, less than the Cutoff Value (NC < CAL10).

If any one of the above criteria is not met, the assay is invalid and must be repeated.

12-INTERPRETATION OF RESULTS (QUALITATIVE PROCEDURE)
In order to interpret results for the MONOLISA™ Anti-HBs EIA by the manual Qualitative Procedure, the Cutoff Value for the assay as well as negative, borderline, and reactive ranges must first be calculated. As described above, the Cutoff Value is calculated as the mean of three 10 mIU/mL Cutoff Calibrators. Additional calculations and interpretive criteria are described below, followed by example results. In the EVOLIS™ Automated Microplate System, the results will be calculated and
interpretation provided by the instrument using the same algorithm.

**Calculations and Interpretation**

**Borderline:** Specimens with antibody levels of 9-11 mIU/mL should be interpreted as borderline, as the specific immune status for those patients can’t be determined without other clinical information or subsequent testing. The borderline interpretation zone is calculated based on the mean of the 10 mIU/mL Cutoff Calibrator. Specimens that are within ± 10% of the Cutoff Calibrator mean O.D. (90% ≤ CAL_{10 \bar{x}} ≤ 110%) are borderline.

For specimens that are borderline, the subject can be re-collected in 2-3 weeks for additional testing. In conjunction with these results, the immune status of subjects should be evaluated based on their clinical status, related risk factors, and other diagnostic test results.

**Reactive:** Specimens with absorbance values greater than the borderline zone (>11 mIU/mL) are considered reactive, and the patient is considered to be immune to infection with HBV. It has not been determined what the clinical significance is for values greater than 11 mIU/mL, other than the individual is considered to be immune to HBV infection.

**Nonreactive:** Specimens with absorbance values less than the borderline zone are considered nonreactive, and the patient is considered to be not immune to infection with HBV. The absorbance value of a specimen must be compared to the borderline zone determined for the microwell plate on which it is assayed.

<tr>
<td></td>
<td>0.215</td>
<td>Reactive</td>
</tr>
</tbody>
</table>

Specimens with absorbance values that are less than 0.000 must be repeated. Those with values greater than the upper linearity limits of the reader should be reported as reactive.

The volume of anticoagulant in sodium citrate tubes causes a specimen dilutional effect. Individuals with borderline results obtained from specimens collected in sodium citrate should be retested using serum specimens.

13-LIMITATIONS

1. For diagnostic purposes, results should be used in conjunction with patient history and other hepatitis markers for diagnosis of acute and chronic infection.

2. A nonreactive test result does not exclude the possibility of exposure to hepatitis B virus.

3. Results obtained with the MONOLISA™ Anti-HBs EIA assay may not be used interchangeably with values obtained with different manufacturers' Anti-HBs assay methods.

4. Results from immunosuppressed patients should be interpreted with caution.

5. This assay does not differentiate between a vaccine-induced immune response and an immune response induced by infection with HBV. To determine if the anti-HBs response is
due to vaccine or HBV infection, a total anti-HBc assay may be performed.

6. Performance characteristics have not been established for therapeutic monitoring.

7. A reactive anti-HBs result does not exclude co-infection by another hepatitis virus.

8. Individuals that have received blood component therapy (e.g., whole blood, plasma, immune globulin administration) during the previous 3 to 6 months may have a false reactive anti-HBs result due to passive transfer of anti-HBs.

9. The performance of the MONOLISA™ Anti-HBs EIA has not been established with cord blood, neonatal specimens, cadaver specimens, heat-inactivated specimens, or body fluids other than serum or plasma, such as saliva, urine, amniotic, or pleural fluids.

14-PERFORMANCE CHARACTERISTICS

A multi-center clinical trial was conducted to evaluate the performance of the MONOLISA™ Anti-HBs Enzyme Immunoassay (EIA) and the MONOLISA™ Anti-HBs Calibrator Kit in human serum and plasma. A total of 1452 prospective subjects at high risk for viral hepatitis and/or showing signs/symptoms of HBV were included in the study. Of these 1452, 1373 were asymptomatic from a high-risk population and 79 reported signs or symptoms of HBV.

Testing to determine the performance characteristics of the MONOLISA™ Anti-HBs EIA and the MONOLISA™ Anti-HBs Calibrator Kit was performed both manually and with the EVOLIS™ Automated Microplate System. Unless otherwise noted, the results which follow summarize the manual testing that was completed.

Expected Values

The expected values that can be seen with the MONOLISA™ Anti-HBs EIA, by gender and age range, were determined during
the evaluation of 1373 prospective asymptomatic subjects. All subjects (100%) were at high risk for viral hepatitis, including intravenous drug users (N = 476), homosexual males (N = 144), sex workers (N = 171), prison history (N = 340), high risk sex partners (N = 167), high risk occupation/health care workers (N = 85), hemodialysis (N = 58), hemophiliacs (N = 3), and other (N = 470). Many had more than 1 high risk behavior or risk factor. One hundred seventy-six (12.8%) of these high risk subjects also reported having received a full course of injections of an HBV vaccine. Subjects in the asymptomatic prospective population were from the following geographic locations: 459 from Los Angeles, CA (33.4%), 57 from Santa Ana, CA (4.1%), 72 from Miami, FL (5.2%), 345 from Cocoa, FL (25.1%), 273 from San Francisco, CA (19.9%), and 167 from Seattle, WA (12.2%). The group was Caucasian (36.5%), Black or African American (41.1%), Hispanic or Latino (13.3%), Asian (4.2%), Native Hawaiian or other Pacific Islander (0.7%), and American Indian or Alaska Native (2.2%), with the remaining 2.0% represented by multiple ethnic groups or was unknown. The subjects were male (70.1%) and female (29.9%) and ranged in age from 18 to 81 years.

The MONOLISA™ Anti-HBs EIA results for the asymptomatic prospective population, by gender and age range, are presented in Table 1.

Reference Markers
The HBV disease classification for each subject in the total prospective population (N = 1452) was determined by a serological assessment using a hepatitis marker profile consisting of FDA-approved commercially available reference EIAs. The six HBV reference marker assays included HBsAg, hepatitis B virus e antigen (HBeAg), total antibody to hepatitis B virus core antigen (Anti-HBc, Total), IgM antibody to hepatitis B virus core antigen (Anti-HBc IgM), total antibody to HBe Ag (Anti-HBe), and total antibody to hepatitis B virus surface antigen (anti-HBs, qualitative or quantitative). All reference EIAs were tested according to the manufacturer’s package insert instructions. Agreement of the MONOLISA™ Anti-HBs EIA was assessed relative to the reference anti-HBs result and to the reference HBV classification.
In the MONOLISA™ Anti-HBs EIA clinical study, across three clinical sites, there were 38 unique reference HBV marker patterns observed. Table 2 summarizes the HBV test patterns and their associated classifications. No other laboratory or clinical information was used in the HBV disease classification process.

Comparison of Results
A comparison of the MONOLISA™ Anti-HBs EIA results with the reference anti-HBs assay for each specimen classification is shown in Table 3. In clinical studies, specimens that had indeterminate results on the reference test were retested in duplicate per the manufacturer’s instructions for use. Any specimens with 2/3 or 3/3 results within the indeterminate range were classified as indeterminate on the reference test.

1  BRD = Borderline (± 10% of cutoff value).
2  Includes specimens that were NRR (not repeatedly reactive).

Overall 567 samples were positive on both assays, 18 samples were indeterminate/borderline on both assays, and 779 samples were negative on both assays.

Percent Agreement
The percent agreement between the MONOLISA™ Anti-HBs EIA and the reference anti-HBs assays was evaluated for each
specimen classification, including the upper and lower 95% Wilson confidence bounds. A summary of this analysis for the prospective population is presented for each HBV classification in Table 4.

</tbody>
</table>

1 N=Total number of samples; refer to Table 3 for correlation of borderline samples. The eighteen specimens that were indeterminate by both assays were not included in percent agreement calculations. Positive or negative results from the MONOLISA™ Anti-HBs EIA were considered as non-agreements in the calculation of percent positive agreement and percent negative agreement when the corresponding reference assay result was indeterminate/borderline.

2 Compares number of samples positive on both assays to sum of all positive samples on the reference assay + samples indeterminate on the reference assay and negative on MONOLISA™ Anti-HBs EIA.

3 Compares number of samples negative on both assays to sum of all negative samples on the reference assay + samples indeterminate on the reference assay and positive on MONOLISA™ Anti-HBs EIA.

The positive percent agreement with the reference method is 94.3% (567/601) with a 95% confidence interval of 92.2 - 95.9%. The negative percent agreement with the reference method is 93.5% (779/833) with a 95% confidence interval of 91.6 - 95.0%.

### Seroconversion Panels

The comparative sensitivity of the MONOLISA™ Anti-HBs EIA was determined by testing 4 commercially available Anti-HBV seroconversion panels and comparing the results to those in the associated certificates of analysis. Comparative results for only panel members near the point of seroconversion are presented in Table 5.
In 2 of the 4 seroconversion panels, the MONOLISA™ Anti-HBs EIA detected reactive levels of hepatitis B surface antibody at the same bleed as the reference anti-HBs EIA. In 1 of the 4 seroconversion panels the MONOLISA™ Anti-HBs EIA detected reactive levels of hepatitis B surface antibody 1 bleed before the reference anti-HBs EIA. One panel was borderline (S/CO = 1.02) on the MONOLISA™ Anti-HBs EIA at the first reactive bleed on the reference test.

Clinical Performance with Individuals Who Received a Full Course of Hepatitis B Vaccine

Retrospective studies were conducted to evaluate a total of 197 serum specimens from 197 subjects who had received a full course of 3 HBV vaccinations (SmithKline-Beecham Biologicals Engerix-B® HBV vaccine or Merck & Co., Inc. Recombivax HB® vaccine). Testing was compared to a reference anti-HBs EIA. The MONOLISA™ Anti-HBs EIA demonstrated immunity in 141/197 specimens or 71.6% (95% confidence interval of 64.9 -
77.4%). The reference method demonstrated immunity in 134/197 specimens or 68.0% (95% confidence interval of 61.2 - 74.1%).

*Two specimens that were indeterminate by both assays were not included in percent agreement calculations.

The positive percent agreement with the reference method is 99.3% (134/135) with a 95% confidence interval of 95.9 - 99.9%. The negative percent agreement with the reference method is 86.7% (52/60) with a 95% confidence interval of 75.8 - 93.1%.

Clinical Performance with Matched Pre- and Post-HBV Vaccination Specimens

In another study, matched sets of pre- and post-vaccination specimens from thirty-eight individuals who had received recombinant HBV vaccine (either SmithKline-Beecham Biologicals Engerix-B® HBV vaccine or Merck & Co., Inc. Recombivax HB® vaccine) were tested with the MONOLISA™ Anti-HBs EIA. The matched sets from each subject included four specimens. One specimen was a pre-vaccination specimen collected before receiving the first vaccination dose of HBV vaccine. The second and third specimens were collected right before the second vaccination dose and third vaccination dose respectively. A post vaccination specimen was collected a minimum of 2 weeks after receiving the full course of 3 injections.

Pre-Vaccination Samples

In pre-vaccination samples, one sample was reactive (immune) on the MONOLISA™ Anti-HBs EIA but nonreactive (not immune) on the reference assay. The negative percent agreement with the
reference method is 97.4% (37/38) with a 95% confidence interval of 86.5 - 99.5%. Results are presented in Table 7 below.

Pre-Second Vaccination Samples
In samples drawn just prior to the second vaccination in the series, the MONOLISA™ Anti-HBs EIA demonstrated immunity in 4/38 (10.5%) of the samples. The reference method demonstrated immunity in 1/38 (2.6%) of the samples.

The positive percent agreement with the reference method is 100% (1/1) with a 95% confidence interval of 20.7 - 100%. The negative percent agreement with the reference method is 89.2% (33/37) with a 95% confidence interval of 75.3 - 95.7%. One sample was borderline on the MONOLISA™ Anti-HBs EIA assay. Results are presented in Table 8 below.

Pre-Third Vaccination Samples
In samples drawn just prior to the third vaccination in the series, the MONOLISA™ Anti-HBs EIA demonstrated immunity in 18/38 (47.4%) of the samples. The reference method demonstrated immunity in 15/38 (39.5%) of the samples.
The positive percent agreement with the reference method is 100% (15/15) with a 95% confidence interval of 79.6 - 100%. The negative percent agreement with the reference method is 82.6% (19/23) with a 95% confidence interval of 62.9 - 93.0%. One sample was borderline on the MONOLISA™ Anti-HBs EIA assay. Results are presented in Table 9 below.

Post-Vaccination Samples
In samples drawn after the complete vaccination series (post vaccination), the positive percent agreement with the reference method is 97.0% (32/33) with a 95% confidence interval of 84.7 - 99.5%. The negative percent agreement with the reference method is 60% (3/5) with a 95% confidence interval of 23.1 - 88.2%. One sample that was immune and two that were not immune with the reference assay were borderline with the MONOLISA™ Anti-HBs EIA. Results are presented in Table 10 below.

Potentially Cross-reactive Medical Conditions
The specificity of the MONOLISA™ Anti-HBs EIA assay was evaluated during the analysis of 393 serum specimens from
individuals with unrelated medical conditions, representing 21 potentially cross-reacting conditions. All of the specimens were anti-HBs negative on another commercially available Anti-HBs assay. The results of each specimen tested on the MONOLISA™ Anti-HBs EIA are summarized in Table 11.

1  Scleroderma, Sjögren’s, MCTD etc.
2  Of the 10 medical condition specimens that were reactive on MONOLISA™ Anti-HBs EIA (excluding HIV-2 positive samples), 3 were reactive on the reference anti-HBs EIA, 5 were nonreactive, and 2 were QNS for additional testing.
3  Two specimens were reactive when tested with another reference anti-HBs EIA; 2 were QNS for additional testing.
4  Specimen was reactive when tested with another reference anti-HBs EIA.

Of the 393 specimens from 21 unrelated medical conditions that were tested, 378/393 (96.2%) were nonreactive on the MONOLISA™ Anti-HBs EIA. Fourteen (14) specimens were reactive: 4 HIV-2 reactive specimens, 2 influenza vaccine specimens, 2 HCV positive specimens, and 1 each of 6 other conditions (CMV, HAV, HIV-1, HTLV, Rubella, and SLE).
Potentially Interfering Substances

The MONOLISA™ Anti-HBs EIA was evaluated for interference according to CLSI Document EP7. None of the interferents at the levels tested below produced a change in clinical interpretation or a significant \( \geq 10\% \) change of the assay.

- Hemolyzed: 500 mg/dL of hemoglobin
- Lipemic: 1000 mg/dL of triglycerides
- Icteric: 20 mg/dL of bilirubin
- Proteinemic: 15 g/dL of protein

The MONOLISA™ Anti-HBs EIA did not detect a high-dose hook effect in patient samples with levels of antibodies to HBsAg as high as 175,000 mIU/mL. The MONOLISA™ Anti-HBs EIA is designed using a two-step format, where a high-dose hook effect is not normally observed.\(^{21}\)

Reproducibility

A 7-member panel consisting of diluted patient specimens in various matrices (serum and EDTA) was tested in duplicate, once a day for 10 days, on 3 lots of the MONOLISA™ Anti-HBs EIA at 3 separate clinical trial sites.

The data from all 3 reagent lots were combined to obtain standard deviation (SD) and percent coefficient of variation (CV) for within run, between run, and total variance. The data were analyzed according to the principles described in CLSI EP15-A2 and ISO/TR 22971:2005. The data summary for this study is shown in Tables 12 and 13.

Quantitative Precision

A precision study was performed with the MONOLISA™ Anti-HBs EIA using quantitative panels prepared in serum and EDTA plasma. Each 7-member panel spanned the linear range of the assay. The 14 specimens were tested in triplicate for 20 days, and results are summarized in Table 14.

Correlation of EVOLIS™ Automated Microplate System with Manual Method

Additional studies have been performed with the MONOLISA™ Anti-HBs EIA on the EVOLIS™ Automated Microplate System and compared to the results of testing with the manual method. In this study, 689 retrospective samples were tested on the MONOLISA™ Anti-HBs EIA, using a total of four (4) EVOLIS™ instruments at three sites. The same samples were tested manually (reference method) on the MONOLISA™ Anti-HBs EIA. The positive, negative, and overall percent agreement, along with the 95% confidence intervals, are presented below. In
determining the percent agreement on borderline results, specimens that were borderline with the reference method (manual testing) and negative with EVOLIS™ were considered as false negative for the EVOLIS™; specimens that were borderline with the reference method and reactive with EVOLIS™ were considered as false positive for the EVOLIS™.

Table 15 - MONOLISA™ Anti-HBs EIA on EVOLIS™ vs. Manual Results

<table>
<thead>
<tr>
<th>EVOLIS™ Results - Anti-HBs</th>
<th>Reactive</th>
<th>Borderline</th>
<th>Nonreactive</th>
<th>Total</th>

<td>689</td>
</tr>
</tbody>
</table>

The positive percent agreement with the reference method, manual testing, is 97.2% (280/288) with a 95% confidence interval of 94.6% - 98.6%. The negative percent agreement with the reference method is 95.8% (384/401) with a 95% confidence interval of 93.3% - 97.3%.

Precision Study

In precision studies, a 10-member panel was tested: four (4) serum samples and six (6) plasma samples (three EDTA samples and three lithium heparin samples). The kit controls and calibrator were also tested for a total of 13 samples. Two replicates each of the thirteen (13) samples were assayed twice a day for 20 days. The data were analyzed following the CLSI guidance EP5A2. The mean ratio, the Standard Deviation (SD), and percent coefficient of variation (%CV) were calculated for each panel member. The data summary is shown in the following table:

¹ Within run: Variability of the assay performance from replicate to replicate
² Between run: Variability of the assay performance from run to run.
³ Between day: Variability of the assay performance from day to day.
⁴ Total: Total variability of the assay performance includes within run, between run, and between day.
⁵ Negative variances were rounded to zero, per statistical convention.
* Note: Specimens with calculated mIU/mL results of less than 5.0 are reported as < 5.0. The SD and %CV cannot be calculated on these samples and therefore are indicated as NA (not applicable).

Reproducibility Study
A 13-member panel consisting of diluted serum and plasma specimens (negative and positive), as well as the kit controls and calibrator, was tested in triplicate, twice a day for 5 days, with the MONOLISA™ Anti-HBs EIA at 3 separate sites. One (1) lot was used at each of the sites. The data from all sites were combined to obtain standard deviation (SD) and percent coefficient of variation (CV) for within run, between run, and between day variance. The data were analyzed according to the principles described in the Clinical Laboratory Standards Institute guidance EP15-A2, revised June 2005. The summaries are shown in the following tables:

15-QUANTITATIVE PROCEDURE:
MONOLISA™ Anti-HBs CALIBRATOR KIT
CATALOG # 25219

INTENDED USE: The MONOLISA™ Anti-HBs Calibrator Kit is intended for manual use and for use with the Bio-Rad EVOLIS™ Automated Microplate System for quantitative determination of anti-HBs in human serum and EDTA, heparin, or citrated plasma. The MONOLISA™ Anti-HBs Calibrator Kit is to be used only with the MONOLISA™ Anti-HBs EIA (Catalog # 25220).

Composition of the MONOLISA™ Anti-HBs Calibrator Kit

<table>
<thead>
<tr>
<th>Component</th>
<th>Contents</th>
</tr>
</thead>
</table>
| C2 Anti-HBs EIA 0 mIU/mL Calibrator 1 vial (1.6 mL) | • 0 mIU/mL of anti-HBs antibodies of human origin  
• Buffer with bovine proteins  
• Preservative: ProClin 950, 0.16%  
• Blue dye |
| C4 Anti-HBs EIA 100 mIU/mL Calibrator 1 vial (1.6 mL) | • 100 mIU/mL of anti-HBs antibodies of human origin  
• Buffer with bovine proteins  
• Preservative: ProClin 950, 0.16%  
• Blue dye |
| C5 Anti-HBs EIA 400 mIU/mL Calibrator 1 vial (1.6 mL) | • 400 mIU/mL of anti-HBs antibodies of human origin  
• Buffer with bovine proteins  
• Preservative: ProClin 950, 0.16%  
• Blue dye |
| C6 Anti-HBs EIA 1000 mIU/mL Calibrator 1 vial (1.6 mL) | • 1000 mIU/mL of anti-HBs antibodies of human origin  
• Buffer with bovine proteins  
• Preservative: ProClin 950, 0.16%  
• Blue dye |

The Calibrators are prepared from human anti–HBs specific immunoglobulins intended for therapeutic use, and are calibrated against WHO reference standard.
WARNINGS

For in vitro diagnostic use only.

1. This test kit should be handled only by qualified personnel trained in laboratory procedures and familiar with their potential hazards. Wear appropriate protective clothing, including lab coat, eye/face protection, and disposable gloves (synthetic, non-latex gloves are recommended) and handle with the requisite Good Laboratory Practices. Wash hands thoroughly after performing the test.

2. Do not smoke, drink, or eat in areas where specimens or kit reagents are being handled.

3. Do not pipette by mouth.

4. The following is a list of potential chemical hazards contained in some kit components (See Section 4 - Reagents):

   a. **WARNING:** Components R3, R4 and R5 contain **0.1% or 0.5% ProClin 300**
      
      
      ![ProClin 300 warning]
      
      H317: May cause allergic skin reaction.
      P280: Wear protective gloves/protective clothing/eye protection/face protection.
      P302 + P352: IF ON SKIN: Wash with plenty of soap and water.
      P333 + P313: If skin irritation or rash occurs: Get medical advice/attention.
      P501: Dispose of contents and container in accordance with local, regional, national, and international regulations.

      **ProClin 300** (0.1% or 0.5%) is a biocidal preservative that is irritating to eyes and skin, may be detrimental if enough is ingested, and may cause sensitization by skin contact; prolonged or repeated exposure may cause allergic reaction in certain sensitive individuals.

   b. **0.005% Gentamicin Sulfate**, a biocidal preservative, which is a known reproductive toxin, photosensitizer, and
sensitizer; prolonged or repeated exposure may cause allergic reaction in certain sensitive individuals.

c. **DANGER!** The **Stopping Solution** (R10) contains **1N Sulfuric Acid**

- **H314**: Causes severe skin burns and eye damage.
- **P290**: May be corrosive to metals.
- **P280**: Wear protective gloves/protective clothing/eye protection/face protection.

**P301 + P330** IF SWALLOWED: Rinse mouth. Do NOT induce vomiting

**P305 + P351** IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.

**P305 + P351** IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing.

**P501**: Dispose of contents and container in accordance to local, regional, national, and international regulations.

The 1N Sulfuric Acid (H₂SO₄) Stopping Solution is severely irritating or corrosive to eyes and skin, depending on the amount and length of exposure; greater exposures can cause eye damage, including permanent impairment of vision. In case of contact with eyes, rinse immediately with plenty of water and seek medical advice. Keep away from strong bases, reducing agents, and metals; do not pour water into this component.

Waste from this material is considered hazardous acidic waste. However, if permitted by local, regional, and national regulations, it can be neutralized to pH 6-8 for non-hazardous disposal if operators are trained and equipped to do so.

5. **MONOLISA™** Anti-HBs EIA contains human blood components. No known test method can offer complete assurance that infectious agents are absent. Therefore, all human blood derivates, reagents, and human specimens should be handled as if capable of transmitting infectious disease, following recommended Standard and Universal
Precautions for bloodborne pathogens as defined by OSHA\textsuperscript{14}, the guidelines from the current CDC/NIH Biosafety in Microbiological and Biomedical Laboratories\textsuperscript{15}, WHO Laboratory Biosafety Manual\textsuperscript{16}, and/or local, regional, and national regulations.\textsuperscript{16-17} The following human blood derivatives are found in Calibrator and/or EIA kit components:

a. Human source material used in the preparation of the Negative Control (C0) and as a diluent for the Positive Control (C1) is nonreactive for detectable hepatitis B surface antigen (HBsAg), and antibodies to hepatitis B core antigen, hepatitis C virus (HCV), and human immunodeficiency viruses (HIV-1 and HIV-2).

b. The human anti-HBs immunoglobulin used in the preparation of the Positive Control (C1) and Calibrators (C2-C6) is a therapeutic grade material which has been inactivated.

c. The human plasma derived viral antigen HBsAg subtypes \textit{ad} and \textit{ay} used in the preparation of the Microplate (R1) and Conjugate Concentrate (R4) are highly purified and heat treated.

6. Biological spills: Human source material spills should be treated as potentially infectious. Spills not containing acid should be immediately decontaminated, including the spill area, materials, and any contaminated surfaces or equipment, with an appropriate chemical disinfectant that is effective for the potential biohazards relative to the samples involved (commonly a 1:10 dilution of bleach, 70-80\% Ethanol or Isopropanol, an iodophor [such as 0.5\% Wescodyne\textsuperscript{TM} Plus], or a phenolic, etc.) and wiped dry.\textsuperscript{18-20} Spills containing acid should be appropriately absorbed (wiped up) or neutralized, wiped dry, and then the area should be decontaminated with one of the chemical disinfectants; materials used to absorb the spill may require biohazardous waste disposal.
NOTE: DO NOT PLACE SOLUTIONS CONTAINING BLEACH INTO THE AUTOCLAVE.

7. Dispose of all specimens and material used to perform the test as though they contain an infectious agent. Laboratory chemical and biohazardous wastes must be handled and discarded in accordance with all local, regional, and national regulations.

8. Complete hazard information and precautions are located in the Safety Data Sheets (SDS) available at www.bio-rad.com and upon request.

PRECAUTIONS FOR USERS
• Do not use calibrators beyond their stated expiration date.
• For the manual pipetting of the calibrators, use individual pipette tips to eliminate carryover of specimens.

REAGENT STORAGE
• Store the MONOLISA™ Anti-HBs Calibrator Kit at 2-8°C.

THE QUANTITATIVE ASSAY PROCEDURE
• The Calibrator Kit is used with the MONOLISA™ Anti-HBs EIA Kit (Catalog # 25220). Dilute each of the four Calibrators in the Calibrator Kit, as well as the EIA kit controls and 10 mIU/mL Cutoff Calibrator, in the MONOLISA™ Anti-HBs EIA Specimen Diluent as described previously in Section 9 - Anti-HBs EIA Procedure. Note: The 1000 mIU/mL Calibrator cannot be used on the EVOLIS™ instrument.
• The plate or partial plate is assayed as described in the EIA Procedure. Read the microwell plate using the 450 nm filter with 615 nm to 630 nm as the reference. (Blank on air.)
• For more concentrated specimens ($A_{450}$ values ≥ that of the 400 mIU/mL Calibrator), the microwell plate may also be read using the 405 nm filter with 615 nm to 630 nm as the reference. Please note that this feature is not available on the EVOLIS™ Automated Microplate System.
Quantitative determinations for patient specimens with concentrations of antibody > 1000 mIU/mL (manual method) or > 400 mIU/ml (EVOLIS™ Automated Microplate System) may be obtained by prediluting in Working Wash Solution. The prediluted samples can then be processed according to the normal assay procedure, by diluting 3:4 in Specimen Diluent. For most specimens, a 1:10 or 1:100 predilution will bring the absorbance within the readable range at A450 or A405, although 1:1000 dilutions may be required for unusually high-titered specimens (> 100,000 mIU/mL).

QUANTITATIVE CALCULATIONS
The method for quantitative calculation of results with the MONOLISA™ Anti-HBs EIA and MONOLISA™ Anti-HBs Calibrator kit are described below. In the EVOLIS™ Automated Microplate System, the results are calculated and interpretation is provided by the instrument using the same algorithm.

A450 Wavelength Reading (for specimens containing ≤ 400 mIU/mL)
• The A450 of three Calibrators from this MONOLISA™ Anti-HBs Calibrator Kit (0, 100, and 400 mIU/mL) along with the A450 of the three separate 10 mIU/mL Cutoff Calibrator values from the MONOLISA™ Anti-HBs EIA kit are graphed versus their assigned concentrations, using linear regression. Please note that the A450 of the 1000 mIU/mL Calibrator cannot be used in this graph, as the absorbance value will be outside the range of the spectrophotometer.
• R² and the equation of the line are determined. R² should be ≥ 0.95. Use the equation of the line to calculate the quantitative results of the specimens. Calculation of results is based on the formula \[\text{mIU/mL} = \frac{(\text{O.D.} - \text{Intercept})}{\text{Slope}}.\] Scale should be set as appropriate to display all the absorbance values for calibrators up to 400 mIU/mL. See example calculations below. (For further assistance in
calculating results using linear regression, contact the Bio-Rad Technical Support staff at 1-800-2-BIORAD.)

- In addition to the quantitative results, specimens with calculated concentrations of **greater than 11 mIU/mL** should be reported as Reactive, those specimens with calculated concentrations of 9-11 mIU/mL should be reported as Borderline, and those with calculated concentrations of less than 9 mIU/mL should be reported as Nonreactive. Specimens with calculated mIU/mL results of less than 5 should be reported as < 5 mIU/mL.

**A405 Wavelength Reading** (for specimens ≥ 400 mIU/mL and ≤ 1000 mIU/mL) – Please note: This feature is not available on the EVOLIS™ Automated Microplate System.

- To determine the concentrations of specimens with higher concentrations of anti-HBs antibodies (≥ 400 mIU/mL to 1000 mIU/mL), the A405 of two Calibrators from the MONOLISA™ Anti-HBs Calibrator Kit (1000 and 400 mIU/mL) can be graphed versus their assigned concentrations, using a linear regression. **The A405 of the 1000 mIU/mL Calibrator must be ≥ 1.3 X A405 of the 400 mIU/mL Calibrator.** The equation of the line is determined, and is used to calculate the concentrations of the specimens. The scale should be set as appropriate to display the absorbance values for Calibrators 400 mIU/mL and 1000 mIU/mL.
• The $A_{405}$ curve is used to determine the concentrations of anti-HBs antibodies in serum or plasma specimens whose concentrations are $\geq 400$ mIU/mL and $\leq 1000$ mIU/mL. This method is not recommended for quantitation of specimens containing $< 400$ mIU/mL. Use the $A_{450}$ method described above. Specimens with concentrations of anti-HBs antibodies greater than 1000 mIU/mL require predilution using Working Strength Wash Solution in the MONOLISA™ Anti-HBs EIA Kit and re-assayed.

VALIDITY CRITERIA FOR THE QUANTITATIVE ASSAY PROCEDURE

A run is valid if the following criteria for the qualitative assay are met:

• The absorbance value of the Positive Control must be greater than or equal to 0.600 AU (PC $\geq 0.600$).
• The individual absorbance value of each 10 mIU/mL Cutoff Calibrator (CAL$_{10i}$) must be greater than or equal to 0.050 and less than or equal to 0.150 AU (0.050 $\leq$ CAL$_{10i}$ $\leq$ 0.150).
• The Cutoff Calibrators must be within the range of 0.65 to 1.35 times the Cutoff Calibrator mean absorbance value.
• The absorbance value of the Negative Control must be greater than 0.000 AU and less than or equal to 0.100 AU (0.000 $<$ NC $\leq$ 0.100).
• The absorbance value of the Negative Control must be less than the mean of the absorbance values of the 10 mIU/mL Cutoff Calibrator, that is, less than the Cutoff Value (NC < CAL$_{10}$).

These additional criteria for the quantitative assay must also be met:

• The square of the correlation coefficient (R$^2$) of the A$_{450}$ calibrator line must be greater than or equal to 0.95.

• The absorbance values at A$_{450}$ for the calibrators in each run must meet the criteria CAL$_{1000}$ > CAL$_{400}$ > CAL$_{100}$ > CAL$_{10}$ > CAL$_0$.

• When using the A$_{405}$ values for reading specimens ≥ 400 mIU/mL, the absorbance value of CAL$_{1000}$ must be ≥ 1.3 X the absorbance value of CAL$_{400}$ (CAL$_{1000}$ ≥ 1.3 X CAL$_{400}$).

• The quantitative value of the Negative Control must be < 9 mIU/mL.

• The absorbance value of the 400 mIU/mL Calibrator must be ≤ 3.500.

</table>
Equation of $A_{450}$ line from Example Graph 1 (for specimens #1 and #2):

$$y = 0.006258x + 0.019504,$$  where

- $y = \text{O.D. (}A_{450}\text{)}$ and
- $x = \text{mIU/mL (unknown)}$

$$x = \frac{(y - 0.019504)}{0.006258}$$

= 10.5 mIU/mL (specimen #1)

= 93.4 mIU/mL (specimen #2)

Equation of $A_{405}$ line from Example Graph 2 (for specimen #3):

$$y = 0.000772x + 0.472333,$$  where

- $y = \text{O.D. (}A_{405}\text{)}$ and
- $x = \text{mIU/mL (unknown)}$

$$x = \frac{(y - 0.472333)}{0.000772}$$

= 464.6 mIU/mL (specimen #3)

**Interpretation of results (Quantitative Assay Procedure)**

**Calculations and Interpretation**

**Borderline:** Specimens with levels of quantitative anti-HBs antibody between 9-11 mIU/mL should be interpreted as borderline, as the specific immune status for those patients can’t be determined without other clinical information or subsequent testing. Borderline results may indicate a low level of antibody that has clinical significance. Specimens that are borderline can be retested or the subject can be re-collected in 2-3 weeks for additional testing. In conjunction with these results, the immune status of subjects should be evaluated based on their clinical status, related risk factors, and other diagnostic test results.
Reactive: Specimens with absorbance values greater than the borderline zone (> 11 mIU/mL) are considered reactive, and the patient is considered to be immune to infection with HBV. It has not been determined what the clinical significance is for values greater than 11 mIU/mL, other than the individual is considered to be immune to HBV infection.

Nonreactive: Specimens with quantitative antibody values less than 9 mIU/mL are considered nonreactive, and the patient is considered to be not immune to infection with HBV. The quantitative antibody value of a specimen must be compared to the borderline zone determined for the plate on which it is assayed.

Specimens with absorbance values that are less than 0.000 must be repeated. Those with values greater than the upper linearity limits of the reader should be reported as reactive.

Quantitative Results for WHO Standard
A series of dilutions of the WHO Standard (WHO First International Reference Preparation for Antibody to HBsAg, 1977) were tested in duplicate on the MONOLISA™ Anti-HBs EIA. The dilutions tested were 1000 mIU/mL, 400 mIU/mL, 200 mIU/mL, 100 mIU/mL, 50 mIU/mL, 10 mIU/mL, and 0 mIU/mL. The mIU/mL values for each of the dilutions was calculated from the calibration curve, as well as the anti-HBs concentration at the assay cutoff. Note: To determine the concentration of specimens with > 400 mIU/mL of anti-HBs antibodies, the assay was read at A405 nm.
**Linearity**

The linearity range (0-1000 mIU/mL) of MONOLISA™ Anti-HBs EIA was assessed by diluting a high-titer patient specimen pool into negative plasma and testing each dilution in duplicate.

**Limit of Detection**

The limit of detection was determined for the MONOLISA™ Anti-HBs EIA by testing 10 replicates of the WHO Standard diluted to 10 mIU/mL and 5 mIU/mL, and Specimen Diluent (0 mIU/mL). In these studies, the lowest amount of anti-HBs in a specimen that could be detected with a 95% probability was calculated to be 4.14 mIU/mL of anti-HBs.
